A201/A026**The Sensitive Gamma-Background and Surface Beta-Contamination Detector**

The tube assembly is connected with the recording unit by a 60 cm long metal tube fitted with a sliding ring and a fixing screw by which the entire assembly is attached to the panoramic head of a camera tripod (Fig. 1). To eliminate the "glasshouse effect" inside the box, 5 holes, 20 mm in diameter, have been bored into the longer side walls and the entire box was covered by glossy white paper. The NNC-223-T meter is fitted with a microammeter with 3 ranges of 0.1, 1 and 10, which in their entire scale-range correspond to dose-rate intensities of 0.5, 5 and 50 mr/h, respectively. The instrument is powered by five MR 19 mercury cells with a total voltage of 6.5 v and a capacity of 3 ampere/hour, capable of operating the instrument for 100 hours. The time constant of the instrument has been increased by the addition of a 5,000 μ F capacitor to decrease the oscillations of the needle. The entire assembly weighs 4.82 kg, of which the tripod weight is 0.9 kg. Numerous measurements have shown that the instrument is capable of furnishing reproducible results. The calibration of the detector relative to the natural background has been made at the sports field adjoining the swimming pool of the Na Bulovce Hospital, using 2 Ra-226 standards made available by the Dosimetrické oddělení (Dosimetric Section). One was the No B-5 standard with an approximate Ra-226 content of 20 mg and a dose intensity of 153 r/cm. hour; the other was the

Card 2/8

A201/A026**The Sensitive Gamma-Background and Surface Beta-Contamination Detector**

No. 10 standard with an approximate Ra-226 content of 1 mg and a dose intensity of 7.54 r/cm · hour. The first standard was placed at a distance of 25 m from the vertical plane of the GM tubes, the other at a distance of 6 m. Due to the directional effect of the GM tubes, the calibration was made from 3 directions: a) with the beam perpendicular to both the plane and the axis of the tubes; b) with the beam forming a 45° angle with the plane and axis of the tubes; c) with the beam forming a 0° angle with the plane and the axis of the tubes. The relation of the values obtained was : a : b : c = 100 : 85.5 : 68.7. The calculated dose intensity of the standard was multiplied by the average of the 3 values (0.857). It was found that for these conditions the value of 0.1 mr/h indicated by the ammeter in the most sensitive (0.1) range corresponded to an actual dose intensity of 7.18 r/h. This meant that the instrument in this arrangement had a sensitivity 14 times greater than in its original arrangement. The calibration was repeated several weeks later under similar conditions yielding exactly the same results. In field measurements the value indicated by the instrument consists of 3 components: a) the internal background of the instrument given by the activity of the tubes, which is relatively low since iron walls are used; b) the unfiltered cosmic radiation dose; c) the gamma radiation dose of the soil. Measurements made at the same place where

Card 3/8

A201/A026**The Sensitive Gamma-Background and Surface Beta-Contamination Detector**

the calibration had been performed yielded on several days always the same value of $12.58 \mu\text{r/h}$ with a deviation of $\pm 3\%$. To eliminate the radiation component of the soil c° , measurements were made on the swimming pool of the hospital on April 8, 1960. The outside dimensions of the swimming pool are $25 \times 15 \text{ m}$, inside dimensions $17 \times 7 \text{ m}$, and the depth is 2.9 m . The swimming pool was refilled for the last time on August 23, 1959, with water from the Vltava River so that any additional radon that might originally have been present had decayed already. Radon formed by the decay of Ra-226 dissolved in the Vltava River water is negligible since this water contains less than $10^{-13} \text{ g Ra-226/liter}$. The detector was placed on a rubber raft, 3.20 m long, 1.25 m wide. The probe with the tubes was extended over the raft board about 30 cm above and parallel to the water level. The lowest value was measured at the center of the pool, viz. 5.74 r/h . This value is then the sum of the a)-internal background of the instrument- and b) -cosmic radiation - components. For the altitude of 260 m above mean sea level, at which the measurements were made and for the geomagnetic latitude of Prague, the unfiltered cosmic radiation produces $2.2 \text{ ion pairs/cm}^3 \cdot \text{sec}$, corresponding to a dose intensity of $3.46 \mu\text{r/h}$. This leaves $2.25 \mu\text{r/h}$ for the internal background of the instrument. Consequently, for

Card 4/8

89374

2/038/60/000/011/003/006
A201/A026**The Sensitive Gamma-Background and Surface Beta-Contamination Detector**

this specific place the natural gamma radiation background (gamma radiation of the soil + cosmic radiation) is $10.3 \mu\text{r}/\text{h}$, or 90.0 mr/year . This figure is in good agreement with values measured abroad in similar environments. The instrument was also tested for its suitability as surface beta-contamination meter. Tl-204 with a maximum energy of 0.76 Mev was used as standard. An accurately measured standard solution of this radioisotope was adequately diluted. Filter paper with an area of 180 cm^2 was soaked in this solution, acquiring a total activity of $1.28 \cdot 10^{-8} \text{ c}$, and a surface activity of $7.1 \cdot 10^{-11} \text{ c/cm}^2$. The paper was placed on an "Umaplex" plate of the same dimension as the lid of the instrument box and covered with a cellophane foil with a surface density of 4.1 mg/cm^2 . The lid of the instrument was then replaced by the plate with the paper facing the tubes. Measurements have shown that the instrument is capable of detecting even lower activities, viz. about $4 \cdot 10^{-11} \text{ c/cm}^2$. It is therefore well suitable for measurements of personnel surface beta-contamination. Since the instability of the mercury cells is practically the only cause affecting the proper operation of the instrument, a portable standard for checking on the operation of the detector has been prepared. The standard uses barium-radium carbonate with a total activity of $3 \text{ to } 5 \cdot 10^{-7} \text{ c Ra-226}$ filled in a sealed glass capillary, 42 mm long, 3 mm in diameter. The capillary is em-

Card 58

A201/A026

The Sensitive Gamma-Background and Surface Beta-Contamination Detector

bedded in an "Umaplex" prism, 50 x 8 x 8 mm, and plugged with an "Umaplex" stopper. Since the standard emits only 4.5 mr/cm² · hour, it can be handled safely without special precaution. For checkings the standard is placed in the center of the instrument-box lid and the value is read from the less sensitive (?) range. In this arrangement the microammeter needle usually deflects over one third to one half of the scale. A photograph of the standard is shown in Figure 3. There are 3 photographs and 9 references: 1 Czech, 1 German and 7 English.

TITLE: Computer setup for the evaluation of biological processes. CZ
Pat. No. PV 5254-62, Class 30a

SOURCE: Vynalezy, no. 11, 1965, 15

TOPIC TAGS: biology, computer, Fourier analysis

ABSTRACT: An Author Certificate has been issued for a device to evaluate biological processes. It has a converter at the input of the tape recorder with an infinite wire loop to register the process observed. At the output of the tape recorder there is a selective circuit to which an analogue counter is attached for the evaluation of the Fourier coefficient. [KP]

TITLE: Instrument for tracing arterial-pulse curves

PERIODICAL: Slaboproudý obzor, v. 23, no. 1, 1962, 51 - 53

TEXT: The article describes an instrument for tracing arterial-pulse curves (sphygmograph), developed as a supplement to the "Elema" electrocardiograph by the ČSAV, Laborator grafických vyšetřovacích metod (Czechoslovak AS, Laboratory of Graphic Methods of Diagnosis). The instrument features a pneumatic device where differential pressures, picked-up by a sensor and a microgauge, are converted into electrical pulses by a semiconductor circuit employing a detuned bridge for amplitude modulation of the carrier wave which is then demodulated in a detector. The sensor, applied to the skin with slight pressure, is a foam-rubber filled rubber pad which is connected by a small rubber hose to a very sensitive microgauge. The microgauge capacity is incorporated into a balanced bridge cir-

✓
Card 1/2

D291/D303

cuit which is fed from an oscillator. Differential voltages, originating from bridge detuning by the variable microgauge capacity, are amplified and led to the phase-discriminating detector. The fully transistorized instrument is battery-fed, very small, and reliable in operation. There are 9 figures.

calf. Comparative test of fresh calf's milk.
Beri-Beritox for calves. Author: the author

ORIG. PUB. : Kolnischko-Verlag, 1959, p. 10, 34-46

ABSTRACT : The amount of protein required
by a vegetative calf in protein which is
supplied from the breast-milk of a cow
is not far from the amount required
by a foal by drinking milk containing 7%
of protein. A definite relationship between
milk by vegetative protein which is lower
than 0.4-0.5%. does not prove satisfactory for
the determination of B-vit. The same
may be recommended as a secondary analysis.

AUTHORS: Kocian, Pavel and Kracík, Jiří, Docent
TITLE: The Conditions of Appearance of a Striated Low-pressure Discharge
PERIODICAL: Slaboproudý obzor, 1961, Vol. 22, No. 1,
pp. 16 - 19

TEXT: It is known that a striated discharge can be obtained if the gas in the discharge tube contains some heavy negative ions. The problem of producing such discharges was investigated experimentally. The discharges were studied in argon, mixed with a compound P-85 which consisted of acetone, amylacetate and nitrocellulose (this material is used as the binder for activating materials on tungsten electrodes). The results of the experiments are shown in six graphs and seven photographs. The conditions of the appearance of a striated discharge were investigated as a function of voltage, diameter of the discharge tube and the total pressure (argon + P-85) and partial pressure of P-85. A typical set of experimental graphs is shown in Fig. 1.

The Conditions of Appearance of a Striated Low-pressure Discharge

These give the discharge current as a function of the total pressure (argon + P-85) at which the striations appear. The measurements were carried out with AC and DC and it was found that in both cases the discharge was of the same type. The discharges represented in Fig. 1 were carried out at various argon pressures (ranging from 0 to 8.1 tor). From the graphs it is concluded that as the pressure of P-85 is increased, i.e. the number of heavy particles is increased, the striations are easier to obtain. On the other hand, when the partial pressure of argon is increased, the ability of the discharge to produce striations is reduced. Thus, at 7 tor pressure (2 tor of argon) the striations appear at 3.3 mA; on the other hand, for the same pressure of P-85 but with argon pressure of 4.1 tor, the striations are obtained at 8.9 mA. The striations can be in the form of a regular or irregular helix or of separate striae. The

The Conditions of Appearance of a Striated Low-pressure Discharge

voltage across the electrodes of the discharge tube as a function of the overall pressure was also investigated for various argon pressures. It was found that, in general, the appearance of the striations could be effected at lower voltages as the partial pressure of P-85 was increased. By measuring the dependence of the discharge current on the diameter of the discharge tube it was found that by increasing the diameter of the tube the striations would be produced more easily than in small-diameter tubes. Rotating striations were also observed over a certain narrow range of currents and pressures but this phenomenon was not investigated in detail. There are 13 figures and 11 references: 5 Czech and 6 non-Czech.

gases

SOURCE: Ceskoslovensky casopis pro fysiku, no. 4, 1965, 328-333

TOPIC TAGS: glow discharge, positive column, gas property, halide, negative ion,
positive ion, electronic circuit

ABSTRACT: The paper gives a survey of the experimental knowledge of a striated positive column in electronegative gases, particularly in certain halides. It points out the different properties of a positive column in such gases compared with those of a column in atomic gases, especially the shape of the striations and their mutual arrangement. It also points out that the changed properties are due to the presence of negative ions and their three dimensional recombination with positive ions. The dependence of the distance between striations on the discharge current, the pressure and the parameters of the electric circuit is investigated experimentally for various gases. The invalidity of Goldstein's law for electronegative gases is proved.

TITLE: Experimental investigation of low-pressure discharge in gases of the 5th, 6th and 7th groups

SOURCE: Sloboproud obzor, v. 23, no. 12, 1964, 608-706

TOPIC TAGS: gas discharge, gas type, low pressure research, gas property

ABSTRACT: (author's Russian and English summaries, modified): Low-pressure discharge in electronegative gases and the volt-ampere response in various gases at different temperatures and tube diameters were investigated experimentally. The obtained responses are compared with those in inert gases, and the differences are explained. Three types of visually discernible low-pressure discharges are described. The positive column is investigated experimentally, and the axial field component is measured in various gases at different pressures and tube diameters. The measurements were made at various points on the circular section of the tube, at the axis as well as near the walls. The obtained values are plotted in a graph as a function of the discharge current. The relations are discussed and compared with similar relations for inert gases. Orig. ext. has: 18 figures, 27 formulas and 15 graphs.

TITLE: The influence of an external magnetic field on the properties of striated discharge

SOURCE: Slaboproudny obzor, v. 25, no. 1, 1964, 44-47

TOPIC TAGS: magnetic field, striated discharge, discharge, homogenous magnetic field, electrons

ABSTRACT: The purpose of this paper is to calculate the dependence of the frequency of the rotation of the striated discharge and its shape (its ascending pitch) on the external homogenous axial magnetic field, and to determine the possibility of influencing this discharge by the above magnetic field. As a starting point the following equations are used: equations for the disturbance of electron concentrations and positive and negative ions in equilibrium, and an equation for the scalar potential disturbance. By solving this system of equations the author obtains the radial distribution of particles, and by discussing the third term in the resulting equation he obtains two relations

AUTHORS: Kracik, J., Kocian, P.**TITLE:** The influence of a magnetic field on the rotation
and shape of threads in a thread discharge**PERIODICAL:** Czechoslovak Journal of Physics, v. 12, no. 9,
1962, 719-720

TEXT: It is known, for example from [1] and [2], that if there is a high-molecular substance in the discharge space of a glow discharge, a thread is produced in the positive column. In the general case the thread is irregular in shape and performs irregular motion. Only in a narrow current and pressure interval can slow uniform rotation of a more or less regular, helical-shaped thread be attained, this being made possible by the intrinsic magnetic field of the discharge. Since the intrinsic magnetic field is small, it follows that the thread, its motion and shape can be influenced by even quite a small external magnetic field. This has been experimentally proved. A substance, known in engineering as P-85 and used for applying an active film to

Card 1/4

The influence of a magnetic field on...

the surface of the electrodes of fluorescent lamps, is located in a cylindrical discharge tube 50 mm in diameter. It is actually a mixture of methyl alcohol acetone, amyl acetate and low nitrocellulose. The pressure of this atmosphere during the experiments was of the order of a tor and the discharge current of the order of 10 mA. An external axial homogeneous magnetic field, regulable in limits of 0-10³ Oe, with a variable polarity, was applied to the discharge space. An analogous problem is solved in paper [3]. Here a study is made of the instability of a discharge in an external magnetic field while the charge, the plasma of which is formed only by electrons and positive ions, is attenuated and rotated by this magnetic field. In our case, however, the conditions are fundamentally different due to the negative ions. The dependence of the frequency of rotation on the magnetic field strength was found. It was proved that the frequency of rotation increased with increasing magnetizing current (Fig. 1). This dependence occurred even when $\omega = 0$ (standing thread). If the thread was in the axis of the tube, it was deflected and rotated when a certain external

Card 2/4

The influence of a magnetic field on...

magnetic field was applied. The dependence of the shape of a regular thread, i.e. a helix, and particularly its pitch, on the intensity of the applied magnetic field was also investigated. Measurements showed that the pitch of the helix decreases with increasing magnetic field (Fig. 2). References: 1) Kracik J., Kocian P.: Czech. J. Phys. Physicochemical and mechanical properties of photoactive polymers materials. V. Šimánek and R. Kudera (Institute of Physics, Academy of Sciences, Czechoslovakia, Prague). Czechoslovak J. Phys. 19, 287-294 (1969). The photoconductivity was studied of the series of optically sensitive (X) of poly(methyl methacrylate) (I), and poly(bromo) methacrylate (II) at 25°C., and simultaneously the deformations (ϵ) were studied, all experiments being carried out at 25°C. For I (II) the value of X is plotted as a function of log(time) for $\epsilon = 97.3-220.3$ kg./sq. cm. (20.8-46.7). The relative change of X in % (ρ) may be expressed as $\rho = k(\ln t) - g$ (k and g being functions of ϵ), the values of k and g being found, for I and II in the studied range of ϵ . The quantity (D) of I (II) is defined as $D_{\text{max}} = (\Delta_e/K_e) \times 10^{-4}$ (cm.⁻¹), where $\Delta_e = \epsilon/\epsilon_0$; the change of D with time is plotted for various ϵ , the value of D for I (II) being found 0.1 (3.0-1.0). X-ray diagrams of II in the charged and uncharged states showed amorphous structures.

Strains Type I Chat and Type 3 W Fox:

Warsaw, Prace nad Epidemiologią, Vol XVI, No 4, 42, pp 377-

Abstract: Author's English summary modified. An epidemiological and virological analysis of poliomyelitis in Poland was made within 6 weeks after completion of oral vaccination with polio virus type I Chat and type 3 W Fox. Investigations made in 1959 and 1960 show the complete safety of Koprowski's attenuated oral vaccine type I Chat. The strain 3 W Fox is indicated as a pathogenic one and its uncertain safety found by investigations in 1960 has been confirmed.

TITLE: Improving the hardness of granulated ammonium nitrate

PERIODICAL: Przemysł chemiczny, v. 40, no. 8, 1961, 439 - 443

TEXT: A description of the investigation carried out at the Zakłady azotowe, Wydział Soli (Nitrogen Works, Salt Department), to improve the keeping properties of granulated NH_4NO_3 which tends to disintegrate into moist crystals, dust and form lumps. A short description of the granulating process is given. Brittleness of the granulate was measured by ball milling 200 g portions (separated from fines <0.5 mm) with 20 g of 4 mm steel shot, in a glass tube 1000 mm long x 70 mm diameter, at the rate of 21 turns/min. The fines (< 0.5 mm) formed after 15 minutes were mechanically sieved off over a period of 2 mins. and their percentage weight was taken as a measure of brittleness of the material. It was found that

hard granules did not suffer from the above-mentioned disintegration during storage, whilst brittle samples crumbled at a rate increasing with brittleness. Fischer's method was used to determine the total water content of the granulate since the weight loss on heating at 105°C for 2 hours yielded values which were ~0.1% too low. Relationships between brittleness and the total moisture content of the granules and the effect of lime and magnesia additions (as nitrates) were examined, finding that brittleness increased sharply with increasing water content. The effect of dolomitic additions was relatively slight. To determine the absorption of atmospheric moisture, 500 l of air of 0-80% relative humidity were passed through 200 g samples of 1.25 - 2.5 mm granules, cooling the latter from 30° to 18°C. It was confirmed that brittleness can be induced by increasing the moisture content of the granulate. From the results obtained, a saltpeter drying plant was constructed on an industrial scale. The possibility of increasing the hardness of granulated NH_4NO_3 by adding ~1% of water-absorbing mine-

rals was investigated. $\text{CaSO}_4 \cdot \frac{1}{2} \text{H}_2\text{O}$ from Cementownia Bolko (Bolko Cement Works), siliceous earth from the region of Piotrowice finely crushed, dehydrated CaCO_3 , and crushed tufa from Filipowice were tried. The experiments were conducted on an industrial scale, mixing powders with liquid saltpeter, in a 2-stage mixer prior to granulating. Cooled granules were coated with various mineral powders and stored for observation. On measuring the brittleness, it was found that mineral additions had, in general, increased granule hardness and inhibited lump formation. Gypsum semihydrate and siliceous earth were best in this respect, while the addition of CaCO_3 resulted in a very weak granulate. Work on the mechanism of these phenomena and on determining physico-chemical properties of the H_2O granulated NH_4NO_3 system is being continued. Apart from the authors, Bolesław Skowroński, Zbigniew Ledzinski, Henryk Maciejec and Edward Jankowiak participated in this investigation.
